

# EBU – Tech 3335 : **Methods of measuring the imaging performance of television cameras for the purposes of characterising and setting**

Alan Roberts, November 2012

## **SUPPLEMENT 006 : Assessment of a Sony PMW 150 camera**

Tests were made on a demonstration model of the Sony PMW-150 HDTV camcorder (serial number 61048) and its manual. Outwardly it appears to be very similar to the PMW EX1, and shares many features with it.

The camera has an integral lens (Fuji, F/1.6, 20:1 4.1~82mm) and records only onto solid-state storage with two SxS slots. The lens has conventional 3-ring control, with manual or automatic operation, but the rings are all servo-driven and have no markings. It has  $3\frac{1}{3}$ " COMS sensors of 1920x1080 pixels, and therefore should qualify as an HDTV camera. Recording HDTV uses MPEG2, 10-bit 4:2:2 1920x1080 at 50Mb/s, 8-bit 4:2:0 1920x1080 at 35Mb/s (with variable bit rate, maximum 35Mb/s), 8-bit 1440x1080 4:2:0 at 35Mb/s (VBR), 8-bit 1280x720 at 35Mb/s VBR, and 8-bit 1440x1080 at 25Mb/s VBR. All the 1080-line modes can be progressive or interlaced at frame rates from 23.976 to 29.97Hz, and 720P up to 60Hz. It can also record in standard SDTV modes, DVCAM. Note that the 50Mb/s mode cannot be used if recording is onto a SDHC card in an adaptor, it must be a proper SxS card (ExpressCard) or a XQD card in an adaptor for this mode.

The camera is quite light (about 2.6kg in including battery) and has an integral monocular viewfinder (852x480) and top-handle mounted screen ( $3\frac{1}{2}$ " LCD, 852x480), and seems aimed at the higher-end professional markets. It has gen-lock and time-code input and outputs, a WiFi adaptor and remote control socket, so may well be usable in multi-camera shoots. Power consumption is about 12 watts at 14.4 volts.

Variable speed recording is possible, from 1 frame/second up to the nominal frame rate setting (24/25/30 when recording 1080-line, 24/25/30/50/60 when recording 720-line).

There are internal menus for setting the performance, not as complex as in a full broadcast camera, but enough to control many of the important features. There are analogue-only video outputs (components and SD-composite via a multi-pin connector which is specific to Sony cameras) and digits via IEEE1394 iLink/Firewire in HDV format, USB-2 for data file transfer, HDMI and 10-bit HDSDI.

The same assessment procedure was used as for other HD cameras, partly attempting to get a good "film-look", and the settings reflect that. In the search for a "film-look" setting it is normal to think of the camera to be mimicking a film camera and telecine, with "best light" transfer to tape, with about 11 stops of tonal range. Assuming that a grading operation will be used in post-production, the settings attempt to give the colourist the same range of options as with film, achieving about 8.3-stop dynamic range. The recommended settings allow about 350% or just under 2 stops of over-exposure relative to normal operation. This is inevitably not as good as can be achieved in  $\frac{2}{3}$ " cameras, and arises from the difference in pixel size (the pixels here are smaller, so sensitivity is maintained at the expense of video noise) and the high sensitivity specification.

The 720p mode is very clean and should be the best way to shoot should the camera be expected to produce an SD output. The quality of this 720p mode is unusually good in this camcorder.

# EBU – Tech 3335 : **Methods of measuring the imaging performance of television cameras for the purposes of characterising and setting**

Alan Roberts, November 2012

## **SUPPLEMENT 006 : Assessment of a Sony PMW 150 camera**

Many of the menu items have little or no effect on image quality. Those that have significant effect are highlighted. The full set of menu items is given for completeness. In boxes with a range of numeric settings, the values indicate the range, and no scales are given. Default settings, where known, are underlined. My recommendations are in the last column, labelled “BBC”, where appropriate. Settings are given for:

- v            Television production
- f            Film-look television

In the tables, items that have an important effect on picture appearance are highlighted with grey background. Rather than just making assertions about performance, I have included measurement results that illustrate the reasons for recommending settings. Virtually all picture control is in the **Profile** menus.

This is not intended as a replacement for reading the manual.

Zoom Speed		Zoom speed for handle zoom control	
High	1 ~ <u>70</u> ~ 99	High setting	
Low	1 ~ <u>30</u> ~ 99	Low setting	
Remote	1 ~ <u>50</u> ~ 99	IR Remote controller setting	
Zoom Transition	<u>Linear</u> , Soft	Zoom start/stop effect	
Interval Rec	On, <u>Off</u>	Stop-frame recording, see manual for details	
Interval Time	<u>1</u> ~ 10, 15, 20, 30, 40 50 sec, 1 ~ 10, 15, 20, 30, 40, 50 min, 1 ~ 4, 6, 12, 24 hour	1 second to 24 hours	
Number of Frames	<u>1</u> , 3, 6, 9	(2, 6, 12 frames in 720p)	
Frame Rec	On, <u>Off</u>		
Number of Frames	<u>1</u> , 3, 6, 9	(2, 6, 12 frames in 720p)	
Clip Cont. Rec	On, <u>Off</u>	Clip continuous recording	
P. Cache Rec	On, <u>Off</u>	Picture cache recording	
Rec Time	<u>0~2.2</u> ~4, 4~6, 6~8, 8~10, 13~15 sec	Defaults to system frame rate	
S&Q Motion	On, <u>Off</u>	Slow and Quick Motion, under/over-cranking	
Frame Rate	1 ~ 60	Defaults to system frame rate	
Rec Review	<u>3sec</u> , 10sec, Clip	Clip plays back entire clip	
TLCS		Total Level Control System, Iris/Gain/Shutter	
Level	+1, +0.5, <u>0</u> , -0.5, -1	Auto Iris stop override	
Mode	Backlight, <u>Standard</u> , Spotlight		
Speed	-99 ~ <u>50</u> ~ 99	Shifting speed	
AGC	On, <u>Off</u>	Automatic gain control	
AGC Limit	3, 6, 9, <u>12</u> , 18dB	Maximum gain AGC can take	12
AGC Point	<u>F/1.8</u> , F/2, F/2.8	Point at which auto-iris/shutter starts in AGC	
Auto Shutter	On, <u>Off</u>		
A.Sht Limit	1/250, 1/500, 1/1000, <u>1/2000</u>	Set shortest shutter	
A.Sht Point	F/2.8, F/3.4, F/4, <u>F/5.4</u>	Point at which iris/shutter starts in Auto Shutter	F/4 <sup>2</sup>

<sup>1</sup> SMPTE or Multi bars are acceptable, Multi appears to be ARIB.

<sup>2</sup> Stopping down beyond F/4 can cause visible softening due to iris diffraction. This is normal for this sensor size.

Shockless White	Off, 1, 2, 3	Speed of white balance response when changed	
White Switch <B>	<u>ATW</u> , Mem	Assign ATW or Memory to white balance position B	
ATW Speed	1, 2, 3, 4, 5	1=slow, 5=fast	
ATW Mode	Natural, Pure		
Wide Conversion	On, <u>Off</u>	Use with lens Wide Angle adaptor	
Steadyshot	<u>On</u> , Off	Set Off when on a tripod	
Image Inversion	<u>Normal</u> , H inv, V inv, Both		
Macro	On, <u>Off</u>		
Auto Black Bal.	Execute, Cancel

Hue	-99 ~ 0 ~ 99	Tweak the sector contents	
Saturation	-99 ~ 0 ~ 99		
White	On, Off	Manual control over white balances	
Offset <A>	-99 ~ 0 ~ 99	Drive bluish to reddish	
Offset <B>	-99 ~ 0 ~ 99		
Offset <ATW>	-99 ~ 0 ~ 99		
Preset White	2100 ~ 3200 ~ 10000	Nominal colour temperature in 100K steps	
HD Detail	On, Off		On {v}, Off {f}
Level	-99 ~ 0 ~ 99		0 {v} <sup>7</sup>
Frequency	-99 ~ 0 ~ 99		+99
Crispening	-99 ~ 0 ~ 99	Noise suppression	0 <sup>8</sup>
H/V ratio	-99 ~ 0 ~ 99	-99=horizontal only, 99=vertical only	0
White Limiter	-99 ~ 0 ~ 99	Limit white overshoots	0
Black Limiter	-99 ~ 0 ~ 99	And black overshoots	0
V DTL Creation	NAM, Y, G, G+R		
Knee APT Level	-99 ~ 0 ~ 99	Sharpen edges that would be lost above the knee	0
SD Detail	On, Off		
Level	-99 ~ 0 ~ 99		
Frequency	-99 ~ 0 ~ 99		
Crispening	-99 ~ 0 ~ 99	Noise suppression	
H/V ratio	-99 ~ 0 ~ 99	-99=horizontal only, 99=vertical only	
White Limiter	-99 ~ 0 ~ 99	Limit white overshoots	
Black Limiter	-99 ~ 0 ~ 99	And black overshoots	
V DTL Creation	NAM, Y, G, G+R		
Knee APT Level	-99 ~ 0 ~ 99	Sharpen edges that would be lost above the knee	
Skin Tone Detail	On, Off		Off
Level	-99 ~ 0 ~ 99	Selected skin tone detail level	
Area Detection	Execute, Cancel	Detect colour in the centre marker	
Area Indication	On, Off	Zebra lights up at the selected colour	
Saturation	-99 ~ 0 ~ 99	Manual skin saturation	
Phase	0 ~ 130 ~ 359	Manual colour phase, degrees	
Width	0 ~ 40 ~ 90	Manual width, degrees	

<sup>7</sup> HD detail could be useful for a film look, but use sparingly, it's vicious. Null action is at about -42, so lower values will soften the pictures. -60 looks nice for film.

<sup>8</sup> This may need adjusting if the camera is used at high gains, set the level to avoid sharpening noise.

Aperture	<u>On</u> , Off	Aperture correction	On
Level	-99 ~ <u>0</u> ~ 99		0
Knee	<u>On</u> , Off	Compress overexposure	On {v}, Off {f}
Auto Knee	<u>On</u> , Off	Auto or manual	Off
Point	50 ~ <u>90</u> ~ 109%	Manual knee break point	85 <sup>9</sup>

<sup>9</sup> Setting level to 85%, slope to -11 gives 1.5 stops headroom, 75% slope +8 gives 2 stops.

<sup>10</sup> Descriptions in the manual seem to fit the idea that these curves are directly copied from other cameras, where Std5=ITU709, Std6=BBC0.4; Std1 has lowest slope near black (for low noise and black-crushing) like a consumer camcorder; Std2has decent gain near black (4.5), Std3 looks like SD ENG, Std4 is SMPTE240M (the old analogue HD standard). The Cine curves are not the “Hypergamma” curves of the PDW700, HDWF900R/790 etc. Cine2 is the only curve suited to production without grading, since it clips at 100%. Cine1 is similar but copes with overexposure by extending beyond 100% video level. Cine3 and 4 differently share the contrast range, use these to taste. If using Cine1, 3 or 4, make sure that video will not be clipped in post-production. Or that grading can cope with the over-voltages.

<sup>11</sup> *Black stretch* (positive values) should be needed only under exceptional conditions, unless the lower-slope Std gamma curves are used, and will increase the noise level. With negative levels, black-crushing will happen, which may be a solution when operating with high video gain levels.

<sup>12</sup> Low Key Sat is useful when video noise levels are high, use a negative amount.

## 2. Measurements

All measurements were made on frames captured onto a SDHC card using an SxS adaptor, no SxS card was immediately available at the time. Thus recordings were made at 35Mb/s 4:2:0 rather than the broadcast level of 50Mb/s 4:2:2. I do not expect the results to be significantly affected by this, except for possible small differences in noise levels. In this section, I shall use the EBU system of designating scanning standards. Live viewing was done on a 32" Grade 1 HDTV CRT monitor and a digital waveform monitor, via the HDSDI output.

### 2.1. Colour performance

Colour performance was assessed visually, using ColorChecker charts. The most accurate colour rendering was obtained using matrix 2 (ITU.709) and Std5 gamma curve (also ITU. 709). The yellow and orange patches were a little desaturated and hues shifted towards green, and the reds and pinks a little over-saturated, but otherwise there was no single colour error large enough to cause a problem. Since there were no "rogue" colours, no further investigation was needed.

### 2.2 Resolution and aliasing

All resolution measurements were made with a circular zone plate test chart. This has 6 circular patterns, each exploring the frequency space of the 1920x1080 limits of HDTV. Each pattern has dc (low frequency) at the centre, and reaches 1920 lines/picture width (960 cycles) horizontally and 1080 lines/picture height (540 cycles) vertically. There is a separate pattern to explore each of R G and B, luma ( $Y'$ ),  $P_b$  and  $P_r$ . Generally, only one quadrant of each pattern is needed since it fully explores both horizontal and vertical frequency spaces.

#### 2.2.1 1920x1080

*Figure 1* shows the luma resolution when the camera detail enhancement was switched off, the native performance of the camera in 1080 progressive scanning. There is no in-band aliasing, and only low-level aliasing centred on 1920 (horizontal) and 1080 (vertical) visible in the smaller double-frequency pattern. This indicates that the lens is delivering some resolution to the camera at twice HD resolution, and that the optical low-pass filter is not quite removing it. Nevertheless, the performance is good.

It is significant that horizontal and vertical resolutions are identical, since it implies that there is no ITU 709 channel filter preceding the video sampling. Although ITU 709 specifies a filter, it is increasingly unlikely to find one in a camera, which means that the pictures are a little too sharp horizontally, which can cause aliasing.

*Figure 2* shows the performance in interlaced 1440x1080i mode. Vertical resolution has softened as expected, and the horizontal resolution dropped to 1440 very cleanly. It is unusual to see down-scaling so well done in a camera.

Clearly the sensors are 1920x1080, as stated in the specification. Also, the optical low-pass filter could have been a little more severe, which would have reduced the aliasing at double-HD frequencies, but the advantage would only be slight.

Figure 1 Resolution 1080P

Figure 2 Resolution 1440x1080i

### 2.2.2 Detail enhancement

The camera hardly needs any enhancement, but it has comprehensive detail manipulation, so they were investigated.

Unusually, the detail level control allows for detail to be reduced as well as increased. This is a significant benefit, particularly when trying to achieve a specific film look. The level control goes from -99 to +99, with factory default at 0, but experiment showed that it has a null effect when set to about -42. There is also an aperture correction function, which is usually found only on top-end cameras. Aperture correction is an equalisation of the basic fundamental camera frequency response, while detail enhancement is best regarded as a user control. Setting aperture level to zero produced a nice, subtle, effect as it should do.

Figure 3 Resolution 1080, aperture correction

Figure 1 Resolution 1080, detail enhancement

Figure 2 Resolution 720p

Figure 3 shows the effect of just aperture correction (level zero) which is recommended for a film look. If the results are still thought to be too sharp, then detail enhancement should be used, with the level control set below -42, even at -99 detail is still visible, but is lowered in level in an acceptable way.

Figure 4 shows the effect of detail enhancement (level zero) which is recommended for video-style shooting. Using higher levels of detail causes significant brightening of lower frequencies, and overshoots on high-contrast edges, both of which can be distracting.

### 2.2.3 1280x720-line

Figure 5 shows the result for 720p shooting, with the video-style detail settings. The down-conversion is very well done; there is virtually no aliasing from the conversion process.

### 2.3 Lens aberrations

In cameras with fixed lenses, it is common to find significant lens aberrations, particularly in the image corners.

Figure 6 shows the results from one corner of a grab at mid zoom and F/4. There is hardly any displacement of the red/green/blue images, just a

Figure 3 Corner aberration

small vertical blue/yellow shift which would be invisible on normal pictures. This is good performance for a small camera.

## 2.4 Video noise

Normally, the main source of video noise in a camera is the analogue circuitry of the camera's front end and the sensors themselves. In many cameras (this being no exception) it is impossible to turn off gamma-correction, and so it can be difficult to get accurate measurements.

Video noise levels were measured by capturing exposures of a white card at four video signal levels, with the camera set to Std5 gamma curve and 0dB gain. 1080P HQ mode was used. *Figure 7* shows the result. Normally, the noise level should follow the slope of the camera gamma curve, with at least 10dB difference between the level near white where the gamma slope is about  $\frac{1}{3}$  and near black where the slope is 4.5, a range of about 22dB.

Figure 4 Noise at 0dB gain

Obviously, that is not happening here. There are several possible causes:

- If the internal processing used too small a bit-depth, the noise distribution would be expected to be rather flat, with only a couple of dB or so between values at 10% and 90% video level. This seems unlikely since the noise floor is significantly higher than would be expected. To see if this is the case, *Figure 8* shows another measurement made at +18dB gain, where any noise floor effect should be circumvented.
- It may be that the ADCs are non-linear or that there is some form of pre-gamma before the ADCs, in order to reduce the bit-depth of the processing. This could account for some of the non-rising noise level near black since the fixed gain-bandwidth product of the analogue amplifiers would reduce the high-frequency content as the gain increases, thereby limiting the noise.
- Permanent noise reduction could be in circuit, which would distort the noise floor.

The rise in noise as signal level falls is obvious, but only 3 to 5dB between 15% and 85% video level, significantly less than expected according to theory. Noise reduction is the most likely cause. But this would imply that, although the output (HDSDI and HDMI, and the 50Mb/s recording mode) is 10-bit, there may be little noise advantage in going to 10-bit recording in this camera, although the vertical chroma bandwidth would improve due to the 4:2:2 subsampling in the 10-bit modes.

Nevertheless, the noise level at 0dB gain is about -45dB, which is just acceptable for a camera in this category. But lowering the camera gain to -6dB will probably not produce any substantial improvement in noise levels.

Figure 5 Noise at +18dB gain

## 2.5 Sensitivity and Dynamic Range

The camera was set to 0dB gain, Std5 gamma (ITU 709) with the knee and white-clipper switched off. It was exposed to a Kodak Gray card (white side, reflectance 90%) and lit to 2000 lux tungsten.

The iris aperture to achieve 100% video level was a little on the open side of F/11, say F/10.5. This is very high for a 1/3" camera and accounts for the rather high noise levels.

The specification claims only a minimum illuminance level of 0.1 lux at 1080/50i, F/1.6 and with 64-frame accumulation, which is hardly likely to produce good pictures. So, the camera was set to +18dB gain, iris fully open (F/1.9 at the focal length used) and the lighting level reduced until the Kodak Gray made exactly 50% video level. The illuminance level was then 1.8 lux, which should be regarded as the usable minimum level. This agrees reasonably well with the specification claim.

The camera was then reset to 0dB gain and exposed to a ColorChecker chart, and the iris adjusted to get exactly 100% video level. The lens aperture was noted as F/6.7. The knee was then switched on, point set low (50%) and slope low such that nothing reached white. The iris was then opened until the white patch was just starting to clip. The slope was then adjusted such that this exposure level exactly reached 100%, and the iris aperture noted as F/3.4. This establishes that the over-exposure headroom which the camera can cope with is just under 2 stops, about 350%, or about 5dB.

If we assume that the lowest usable exposure level as that at which wanted detail has the same magnitude as the RMS value of the noise, -45dB near black, then the total available dynamic range must be 45+5=50dB, or 8.3 stops.

In a broadcast 2/3" camera, headroom of about 2 stops and an overall range of about 11 stops is common. That this camera has about 350% headroom, a little under 2 stops, indicates that the head-amplifier gains are quite high, which also explains the high sensitivity figure and the rather high noise levels.

## 2.6 Motion effects

The camera has CMOS sensors and can therefore be expected to show geometrical distortion on moving objects, the 'rolling shutter effect'.

It was exposed to a small electric fan, speed-adjusted to strobe with the television scanning rate. *Figure 9* shows part of one frame, with the shutter set to 1/250 second. The blade on the left (going up) is shrunk in width by about 50% while that on the right (going down) is approximately doubled in width. This indicates that there are no processing tricks in the camera to ameliorate the effect. So 'flash-banding' will be a problem with this camera, as with most other small CMOS cameras, where still-camera flashes will illuminate only a part of the field or frame, and intra-frame motion may be disturbing.

Figure 6 Rolling shutter effect

## 2.7 Conclusion

The camera could qualify for Tier 2L (Long Form) or 2J (Journalism) according to EBU R118, but only just. The noise level is rather high and very near the limit for both tier levels.

Resolution is good, alias levels are very low, and 720P performance is particularly good for a small camera.

The total dynamic range is only 8.3 stops, which is typical for a camera of this size, and is directly related to the high sensitivity.

Motion artefacts from the 'rolling shutter' are as expected for a normal CMOS camera.

Alan Roberts, November 2012

## **SUPPLEMENT 005 : Assessment of a Sony PMW 200 camera**

Tests were made on a production model of the Sony PMW-200 HDTV camcorder (serial number 400033) and its manual. Outwardly it appears to be very similar to the PMW EX1, and shares many features with it.

The camera has an integral lens (Fuji, F/1.9, 14:1 5.8~81.2mm) and records onto solid-state storage SxS cards (or other card types via adaptors). The lens has conventional 3-ring control, with manual or automatic operation, but the rings are ‘real’ in that they directly control the lens and have calibration markings. It has 3 ½” CMOS sensors of 1920x1080 pixels, and therefore should qualify fully as an HDTV camera. Recording HDTV uses MPEG2, 10-bit 4:2:2 1920x1080 at 50Mb/s, 8-bit 4:2:0 1920x1080 at 35Mb/s (with variable bit rate, maximum 35Mb/s), 8-bit 1440x1080 4:2:0 at 35Mb/s (VBR), 8-bit 1280x720 at 35Mb/s VBR, and 8-bit 1440x1080 at 25Mb/s VBR. All the 1080-line modes can be progressive or interlaced at frame rates from 23.976 to 29.97Hz, and 720P up to 60Hz. It can also record in standard SDTV modes, DVCAM. Note that the 50Mb/s mode cannot be used if recording is onto a SDHC card in an adaptor, it must be a proper SxS card (ExpressCard or XQD card via an adaptor) for this mode.

The camera is quite light (about 2.7kg in including battery) and has an integral monocular viewfinder (852x480) and top-handle mounted screen (3½” LCD, 852x480), and seems aimed at the high-end professional and full broadcast markets. It has gen-lock and time-code input and outputs, a WiFi adaptor and remote control socket, so may well be usable in multi-camera shoots. Power consumption is about 12 watts at 14.4 volts.

Variable speed recording is possible, from 1 frame/second up to the nominal frame rate setting (24/25/30 when recording 1080-line, 24/25/30/50/60 when recording 720-line).

There are internal menus for setting the performance, not as complex as in a full broadcast camera, but enough to control many of the important features. There are analogue-only video outputs (components and SD-composite via a multi-pin connector which is specific to Sony cameras) and digits via IEEE1394 iLink/Firewire in HDV format, USB-2 for data file transfer, HDMI and 10-bit HDSDI.

The same assessment procedure was used as for other HD cameras, partly attempting to get a good “film-look”, and the settings reflect that. In the search for a “film-look” setting it is normal to think of the camera to be mimicking a film camera and telecine, with “best light” transfer to tape, with about 11 stops of tonal range. Assuming that a grading operation will be used in post-production, the settings attempt to give the colourist the same range of options as with film, achieving about 9.5-stop dynamic range. The recommended settings allow about 2.5 or 1.5 stops of over-exposure relative to normal operation. This is not quite as good as can be achieved in ⅔” cameras, and arises from the difference in pixel size (the pixels here are smaller, so sensitivity is maintained at the expense of highlight handling and video noise) and high sensitivity specification.

The 720p mode is very clean and should be the best way to shoot should the camera be expected to produce an SD output.

# EBU – Tech 3335 : **Methods of measuring the imaging performance of television cameras for the purposes of characterising and setting**

Alan Roberts, November 2012

## **SUPPLEMENT 005 : Assessment of a Sony PMW 200 camera**

Many of the menu items have little or no effect on image quality. Those that have significant effect are highlighted. The full set of menu items is given for completeness. In boxes with a range of numeric settings, the values indicate the range, and no scales are given. Default settings, where known, are underlined. My recommendations are in the last column, labelled “Pref”, where appropriate. Settings are given for:

- v Television production
- f Film-look television

In the tables, items that have an important effect on picture appearance are highlighted with grey background. Rather than just making assertions about performance, I have included measurement results that illustrate the reasons for recommending settings. Virtually all picture control is in the **Profile** menus.

This is not intended as a replacement for reading the manual.

<sup>5</sup> EDF isn't available when recording to SDHC card in an adaptor, which means you can't get the 50Mb/s mode.

<sup>6</sup> The EBU's preferred nomenclature is to describe the frame dimensions first, followed by a letter to indicate interlace or progressive, then a right slash and the frame rate. Thus, what is here called HQ 1080/50i would be called, by the EBU, 1920x1080i/25.

<sup>8</sup> HD detail could be useful for a film look, but use sparingly, it's vicious. Null action is at about -42, so lower values will soften the pictures. -60 looks nice for film.

<sup>9</sup> This may need adjusting if the camera is used at high gains, set the level to avoid sharpening noise.

<sup>10</sup> Setting level to 85%, slope to -14 gives 1.5 stops headroom, 75% slope +10 gives 2.5 stops.

<sup>11</sup> Descriptions in the manual seem to fit the idea that these curves are directly copied from other cameras, where Std5=ITU709, Std6=BBC0.4; Std1 has lowest slope near black (for low noise and black-crushing) like a consumer camcorder; Std2has decent gain near black (4.5), Std3 looks like SD ENG, Std4 is SMPTE240M (the old analogue HD standard). The Cine curves are not the “Hypergamma” curves of the PDW700, HDWF900R/790 etc. Cine2 is the only curve suited to production without grading, since it clips at 100%. Cine1 is similar but copes with overexposure by extending beyond 100% video level. Cine3 and 4 differently share the contrast range, use these to taste. If using Cine1, 3 or 4, make sure that video will not be clipped in post-production. Or that grading can cope with the over-voltages.

<sup>12</sup> *Black stretch* (positive values) should be needed only under exceptional conditions, unless the lower-slope Std gamma curves are used, and will increase the noise level. With negative levels, black-crushing will happen, which may be a solution when operating with high video gain levels.

<sup>13</sup> *Low Key Sat* is useful when video noise levels are high, use a negative amount.

## 2 Measurements

All measurements were made on frames captured onto a SDHC card using an SxS adaptor, no SxS card was immediately available at the time. Therefore, recordings were made at 35Mb/s rather than the top-end 50Mb/s. I do not expect the test results to be affected by this, except for possible slight differences in noise levels. In this section, I shall use the EBU system of designating scanning standards. Live viewing was done on a 32" Grade 1 HDTV CRT monitor and a digital waveform monitor, via the HDSDI output.

### 2.1 Colour performance

Colour performance was assessed visually, using ColorChecker charts. The most accurate colour rendering was obtained using matrix 2 (ITU.709) and Std5 gamma curve (also ITI. 709). The yellow and orange patches were a little desaturated and hues shifted towards green, and the reds and pinks a little over-saturated, but otherwise there was no single colour error large enough to cause a problem. Since there were no "rogue" colours, no further investigation was needed.

### 2.2 Resolution and aliasing

All resolution measurements were made with a circular zone plate test chart. This has 6 circular patterns, each exploring the frequency space of the 1920x1080 limits of HDTV. Each pattern has dc (low frequency) at the centre, and reaches 1920 lines/picture width (960 cycles) horizontally and 1080 lines/picture height (540 cycles) vertically. There is a separate pattern to explore each of R G and B, luma (Y'), P<sub>b</sub> and P<sub>r</sub>. Generally, only one quadrant of each pattern is needed since it fully explores both horizontal and vertical frequency spaces.

#### 2.2.1 1920x1080

*Figure 1* shows the luma resolution when the camera detail enhancement was switched off, the native performance of the camera in 1080 progressive scanning. There is no in-band aliasing, and only low-level aliasing centred on 1920 (horizontal) and 1080 (vertical) visible in the smaller double-frequency pattern. This indicates that the lens is delivering some resolution to the camera at twice HD resolution, and that the optical low-pass filter is not quite removing it. Nevertheless, the performance is good.

It is significant that horizontal and vertical resolutions are identical, since it implies that there is no ITU 709 channel filter preceding the video sampling. Although ITU 709 specifies a filter, it is increasingly unlikely to find one in a camera, which means that the pictures are a little too sharp horizontally, which can cause aliasing.

*Figure 2* shows the performance in interlaced mode. Vertical resolution has softened as expected, but nothing else has changed. Resolution is still very good.

Clearly the sensors are 1920x1080, as stated in the specification. Also, the optical low-pass filter could have been a little more severe, which would have reduced the aliasing at double-HD frequencies, but the advantage would only be slight.

**Figure 1 Resolution 1080**

**Figure 2 Resolution 1080i**

Figure 3 shows the resolution in the 1440x1080 modes.

Oddly, there is a significant increase in vertical aliasing, rather than horizontal. The down-conversion from 1920 to 1440 is very well done, so it is a mystery why the vertical aliasing should suffer in this mode. Clearly there is some odd processing going on in the camera.

### 2.2.2 Detail enhancement

The camera hardly needs any enhancement, but it has comprehensive detail manipulation, so they were investigated.

Unusually, the detail level control allows for detail to be reduced as well as increased. This is a significant benefit, particularly when trying to achieve a specific film look. The level control goes from -99 to +99, with factory default at 0, but experiment showed that it has a null effect when set to about -42. There is also an aperture correction function, which is usually found only on top-end cameras. Aperture correction is an equalisation of the basic fundamental camera frequency response, while detail enhancement is best regarded as a user control. Setting aperture level to zero produced a nice, subtle, effect as it should do.

Figure 3 Resolution 1440x1080i

Figure 5 Resolution 1080, aperture correction

Figure 5 Resolution, 1080, detail and aperture

Figure 4 shows the effect of just aperture correction (level zero) which is recommended for a film look. If the results are still thought to be too sharp, then detail enhancement should be used, with the level control set below -42, even at -99 detail is still visible, but is lowered in level in an acceptable way.

Figure 5 shows the effect of aperture correction and detail enhancement (both at level zero) which is recommended for video-style shooting. Using higher levels of detail causes significant brightening of lower frequencies, and overshoots on high-contrast edges, both of which can be distracting.

### 2.2.3 1280x720-line

Figure 6 shows the result for 720p shooting, with the video-style detail settings. The down-conversion is very well done; there is virtually no

Figure 6 Resolution 720p

aliasing from the conversion process.

### 2.3 Lens aberrations

In cameras with fixed lenses, it is common to find significant lens aberrations, particularly in the image corners.

Figure 7 shows the results from one corner of a grab at mid zoom and F/4. There is hardly any displacement of the red/green/blue images, just a small vertical blue/yellow shift which would be invisible on normal pictures. This is good performance for a small camera.

Figure 7 Lens aberrations

### 2.4 Video noise

Normally, the main source of video noise in a camera is the analogue circuitry of the camera's front end and the sensors themselves. In many cameras (this being no exception) it is impossible to turn off gamma-correction, and so it can be difficult to get accurate measurements.

Video noise levels were measured by capturing exposures of a white card at four video signal levels, with the camera set to Std5 gamma curve and 0dB gain. 1080P HQ mode was used. Figure 8 shows the result. Normally, the noise level should follow the slope of the camera gamma curve, with at least 10dB difference between the level near white where the gamma slope is about 1/3 and near black where the slope is 4.5, a range of about 22dB.

Obviously, that is not happening here.

If the internal processing used too small a bit-depth, the noise distribution would be expected to be rather flat, with only a couple of dB or so between values at 10% and 90% video level, and this is what we see here. So, the implication is that the signal processing bit-depth is limited, and causing a noise-floor level below which the noise will not go, even if the analogue noise level falls. To see if this is the case, Figure 9 shows another measurement made at +18dB gain, where any noise floor effect should be circumvented.

The rise in noise as signal level falls is obvious, about 10dB between 15% and 85% video level, more or less as expected according to theory. There are several possible causes for this:

- Noise reduction is 'flattening' the noise distribution,
- Limited processing bit-depth is providing a 'noise floor',
- The ADCs are non-linear or there is some form of pre-gamma before the ADCs.

From these tests, it is impossible to tell which cause is true. The third would show as a reduction in resolution as gain is increased.

Figure 8 Noise distribution, 0dB gain

Figure 9 Noise distribution, +18dB gain

Nevertheless, the noise level at 0dB gain is about -48dB, which is quite acceptable for a camera in this category. But lowering the camera gain to -6dB will not produce a substantial change in noise levels.

## 2.5 Sensitivity and Dynamic Range

The camera was set to 0dB gain, Std5 gamma (ITU 709) with the knee and white-clipper switched off. It was exposed to a Kodak Gray card (white side, reflectance 90%) and lit to 2000 lux tungsten. The iris aperture to achieve 100% video level was a little on the closed side of F/11, say F/11.7. This is very high for a 1/2" camera and accounts for the rather high noise levels.

The specification claims only a minimum illuminance level of 0.12 lux at 1080/59.94i, F/1.8 and with 64-frame accumulation, which is hardly likely to produce good pictures. So, the camera was set to +18dB gain, iris fully open (F/1.9 at the focal length used) and the lighting level reduced until the Kodak Gray made exactly 50% video level. The illuminance level was then 1.8 lux, which should be regarded as the usable minimum level. This agrees well with the specification claim.

The camera was then reset to 0dB gain and exposed to a ColorChecker chart, and the iris adjusted to get exactly 100% video level. The lens aperture was noted as slightly open from F/8, say F/7.5. The knee was then switched on, point set low (50%) and slope low such that nothing reached white. The iris was then opened until the white patch was just starting to clip. The slope was then adjusted such that this exposure level exactly reached 100%, and the iris aperture noted as a little open from F/4, say F/3.5. This establishes that the over-exposure headroom which the camera can cope with is just over 2 stops, about 500%, or about 8dB.

If we assume that the lowest usable exposure level as that at which wanted detail has the same magnitude as the RMS value of the noise, -48.5dB near black, then the total available dynamic range must be  $48.5+8=56.5$ dB, or 9.4 stops.

## 2.6 Motion effects

The camera has CMOS sensors and can therefore be expected to show geometrical distortion on moving objects, the 'rolling shutter effect'.

It was exposed to a small electric fan, speed-adjusted to strobe with the television scanning rate. *Figure 10* shows part of one frame, with the shutter set to 1/250 second. The blade on the left (going up) is shrunk in width by about 50% while that on the right (going down) is approximately doubled in width. This indicates that there are no processing tricks in the camera to ameliorate the effect. So 'flash-banding' will be a problem as with all CMOS cameras, where stills-camera flashes will illuminate only a part of the field or frame, and intra-frame motion may be disturbing.

Figure 10 Rolling shutter effect

## 2.7 Conclusion

The camera should qualify for Tier 2L (Long Form) according to EBU R118, in that it passes all the advisory criteria, although individual broadcasters are free to assign tiering to cameras.

Resolution is good, alias levels are very low, and 720P performance is good.

The dynamic range of 9.4 stops is a little on the low side as a result of the rather high noise levels.

Motion artefacts from the 'rolling shutter' are as expected for a CMOS camera.
